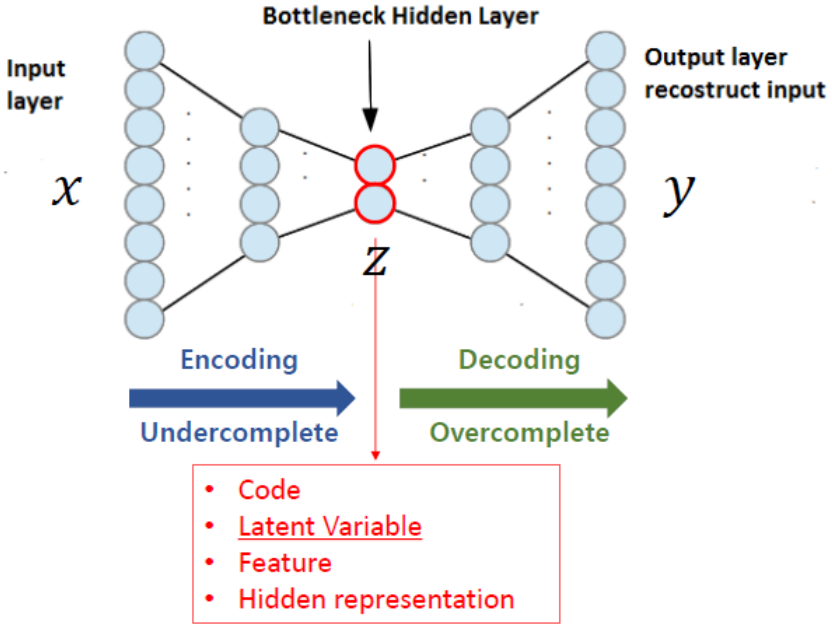
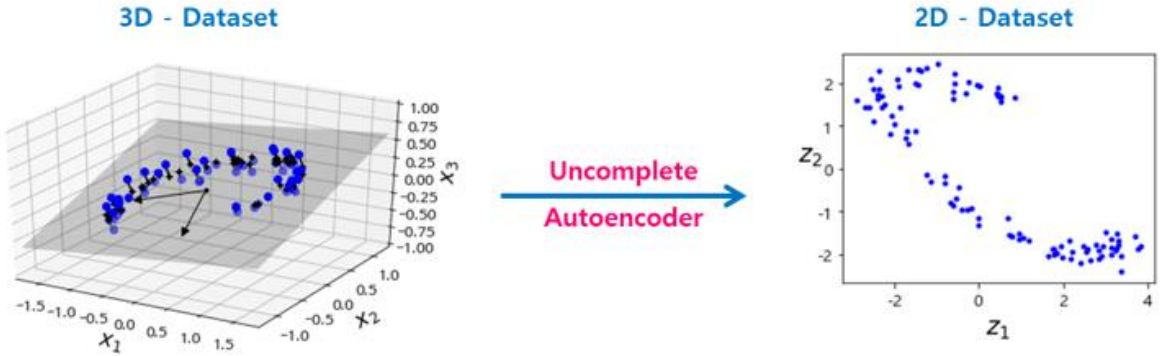
Contents

- Autoencoders
- Variational Autoencoder (VAE)
- GANs

Autoencoders

- **Autoencoder**
  - To learn a representation (encoding) for training data set (dimensionality reduction) by training the network to ignore signal "noise", in other words, feature extraction.
  - Focus on the encoder.





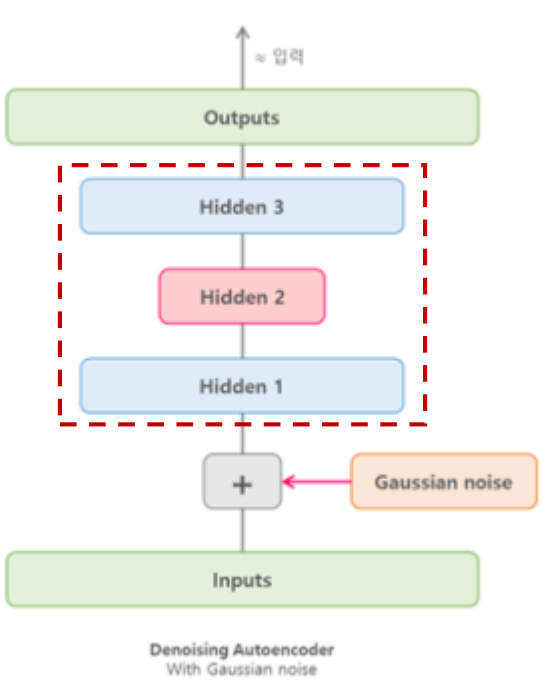
http://videolectures.net/deeplearning2015_vincent_autoencoders/?q=vincent%20autoencoder

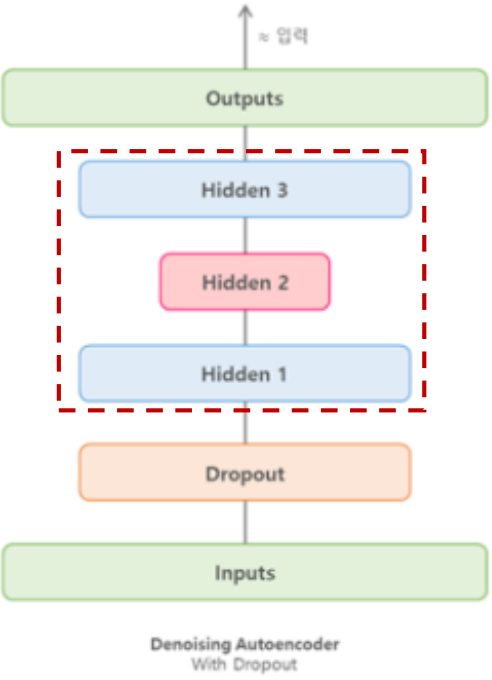
Autoencoders

- **Applications of Autoencoders**
  - Dimensionality reduction
  - Anomaly detection
  - Image denoising
  - Image compression
  - Image generation

Denoising Autoencoder

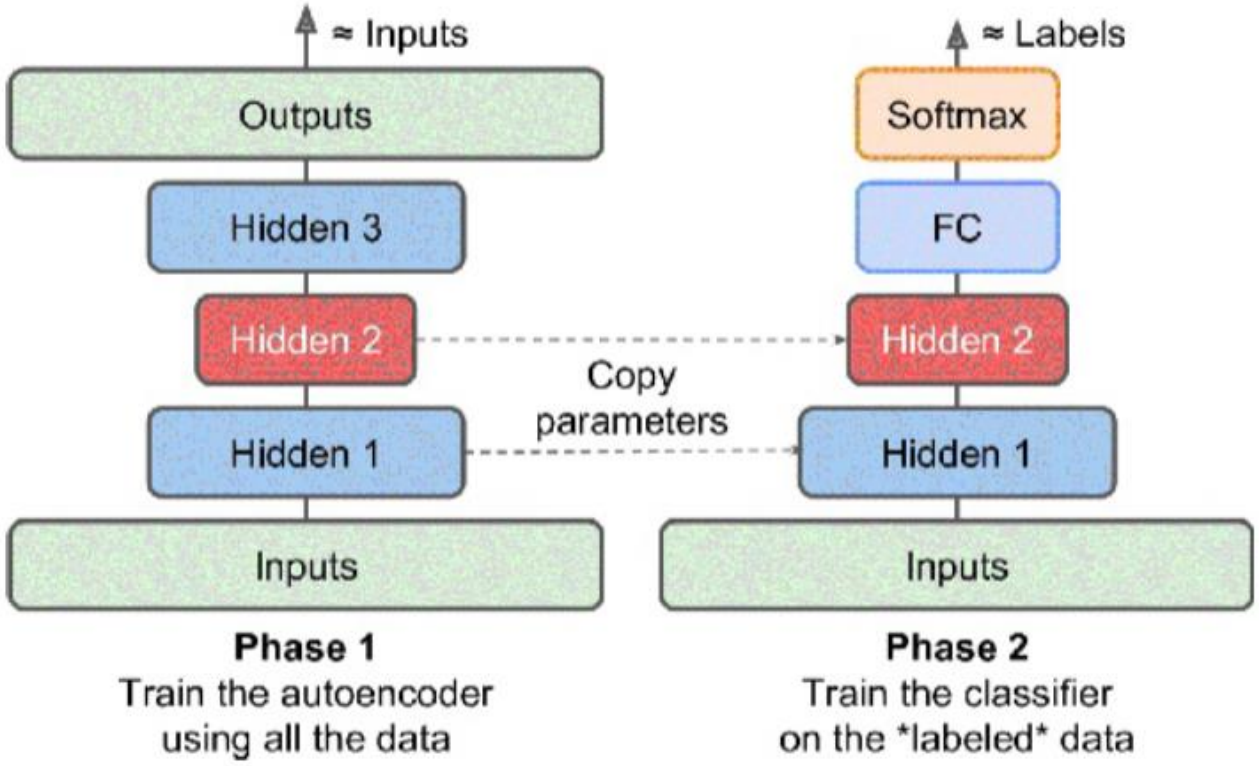
- **Denoising Autoencoder**
  - Add noise to the input and learn to reconstruct the original input without noise
  - Noise can be generated in random input units using Gaussian Noise or Dropout.





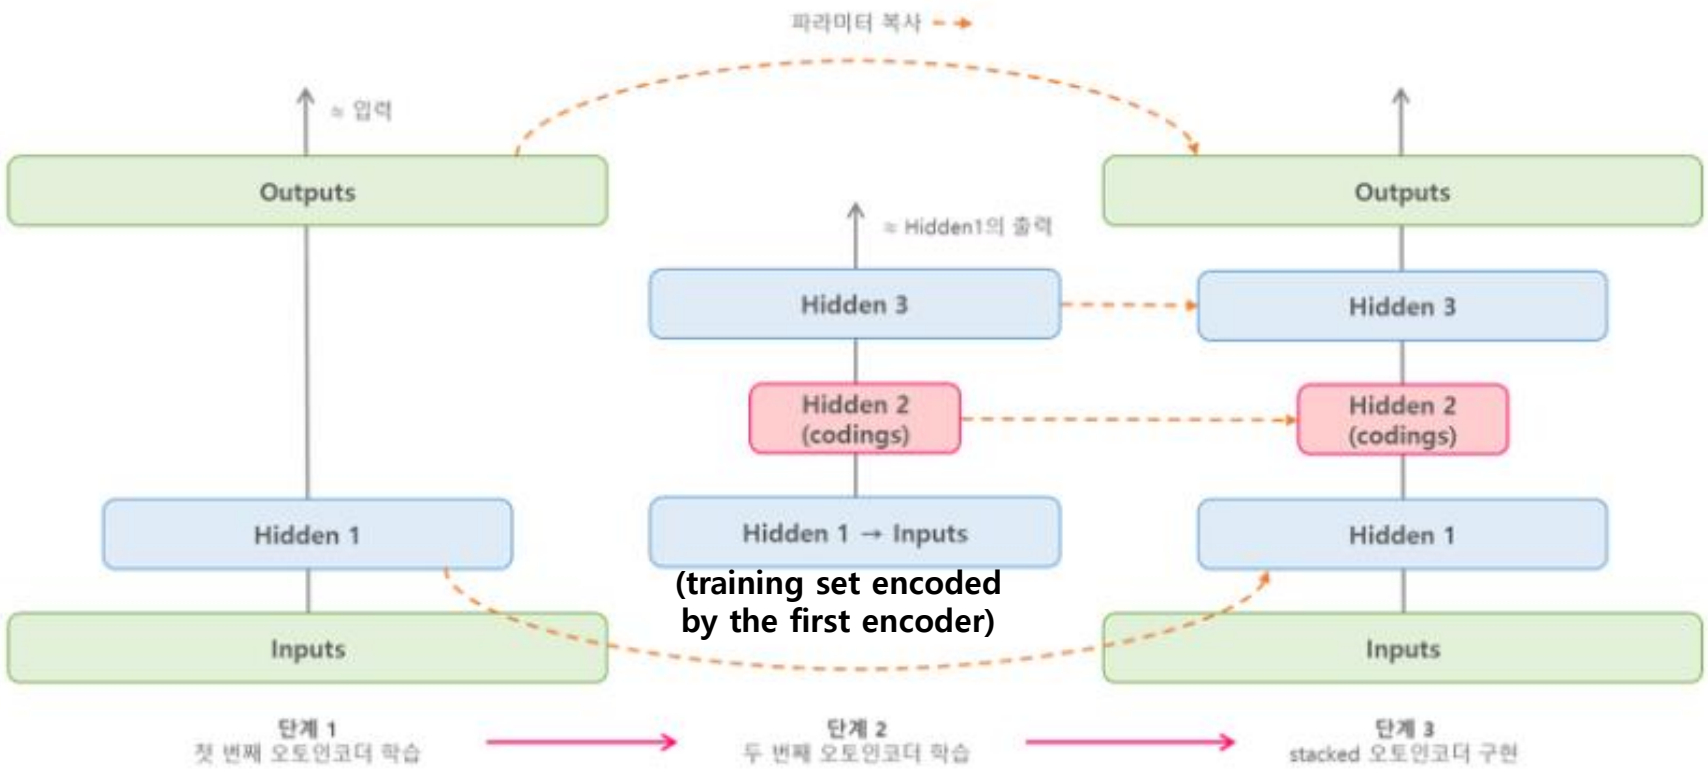
Stacked (or deep) Autoencoder

- **Unsupervised Pre-training using Stacked Autoencoders**
  - When you have a complex supervised task but you do not have enough labeled training data (labeling is time-consuming and costly)



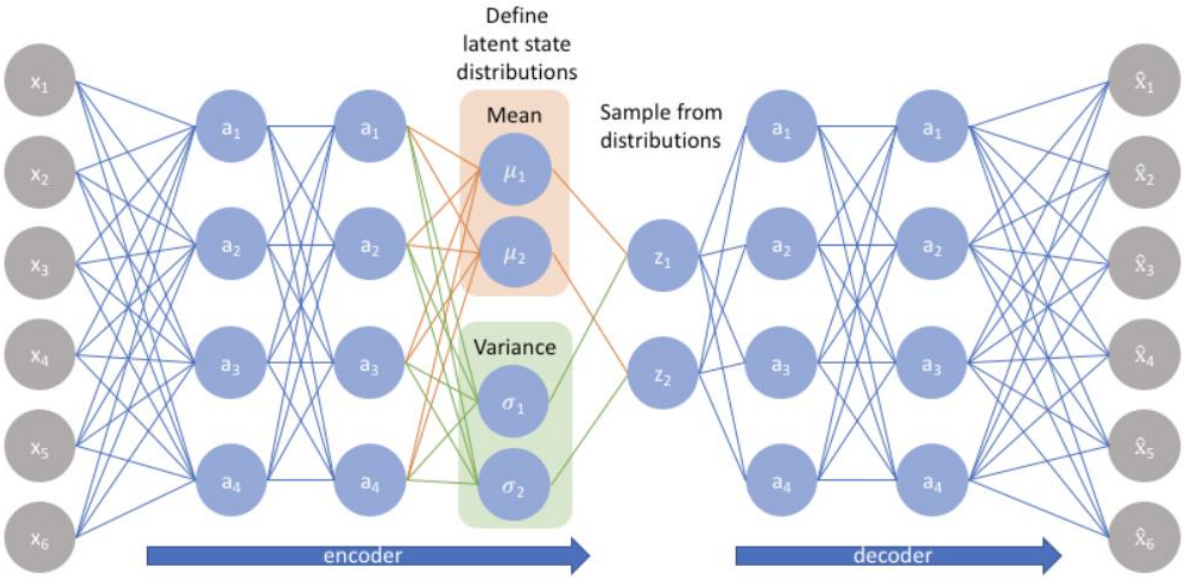
Stacked Autoencoder

- **Training One Auto-encoder at a time**
  - Rather than training the whole stacked auto-encoder in one go, it is much faster to train one shallow auto-encoder at a time, then stack all of them into a single. (not used as much these days)



Deep Learning

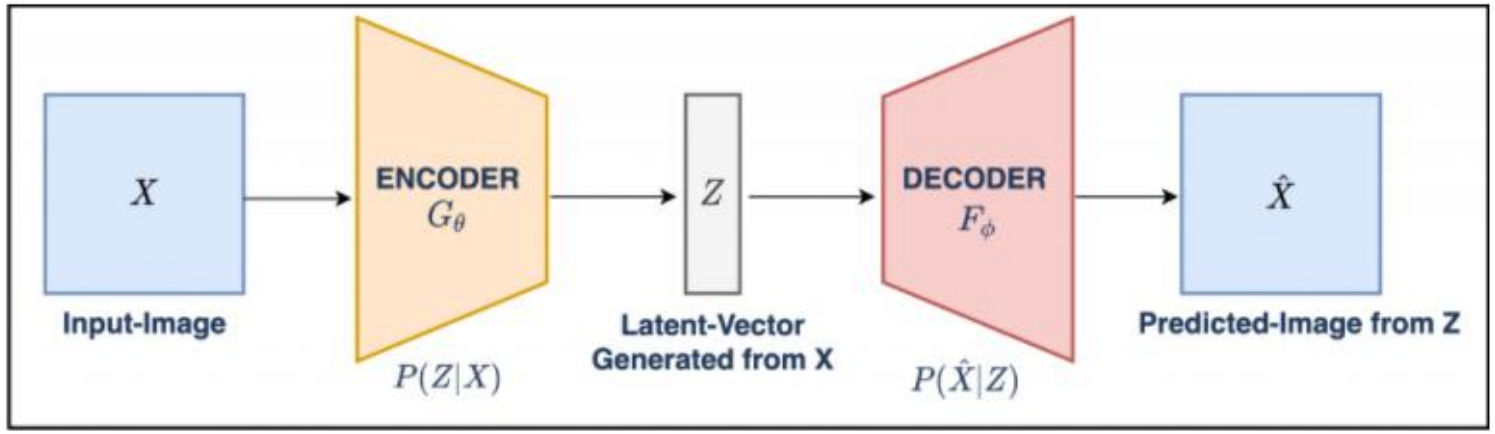
- **Variational Autoencoder (VAE)**
  - Provides a probabilistic manner for describing an observation in latent space
  - Encoder is formulated to describe a probability distribution for each latent attribute
  - Encoder is referred to as recognition model, and decoder is referred to as the generative model



Autoencoders

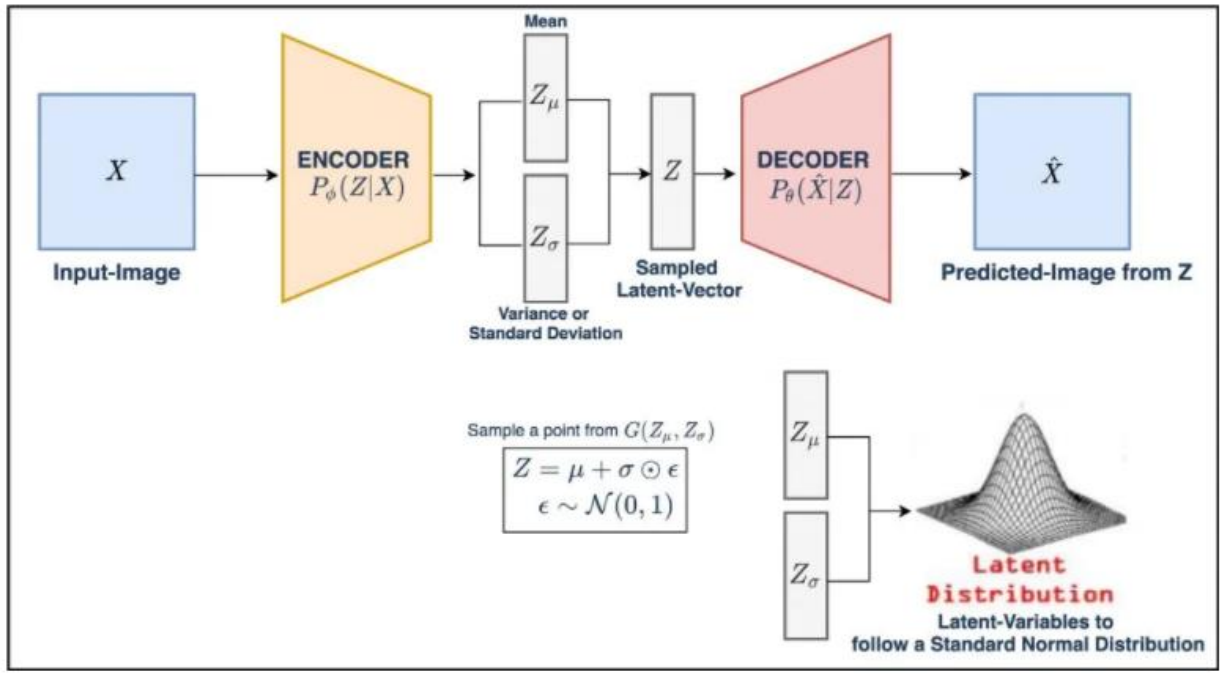
- **Auto-encoder**
  - **Reconstruction loss (MSE)** = $\frac{1}{N}\sum_{i=1}^{N}(X_i - \hat{X}_i)^2$ (N is number of images in a batch)

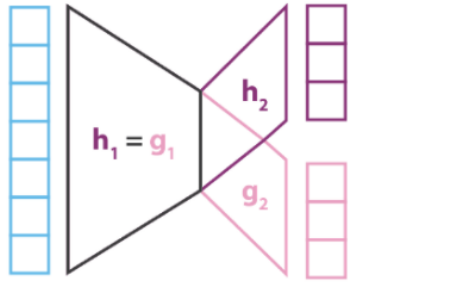
  - It is not good at generating new images because of its latent space structure:
    - The latent space was not continuous and did not allow easy interpolation.
    - Encoded vectors are grouped in clusters corresponding to different data classes, and there are huge gaps between the clusters.
    - While generating a new sample, the decoder often produces a gibberish output if the chosen point in the latent space did not contain any data



Variational Autoencoder (VAE)

- A probabilistic and generative model (focus on the decoder)
- Instead of mapping the image on a point in space, the encoder of VAE maps the image onto a normal distribution.
- Sample a latent vector Z from two latent variables Z_μ and Z_σ (also called a sampling-layer)
- We want the latent vector Z to follow a standard normal distribution. (Z_μ and Z_σ should be trained such that they are close to 0 and 1 respectively)

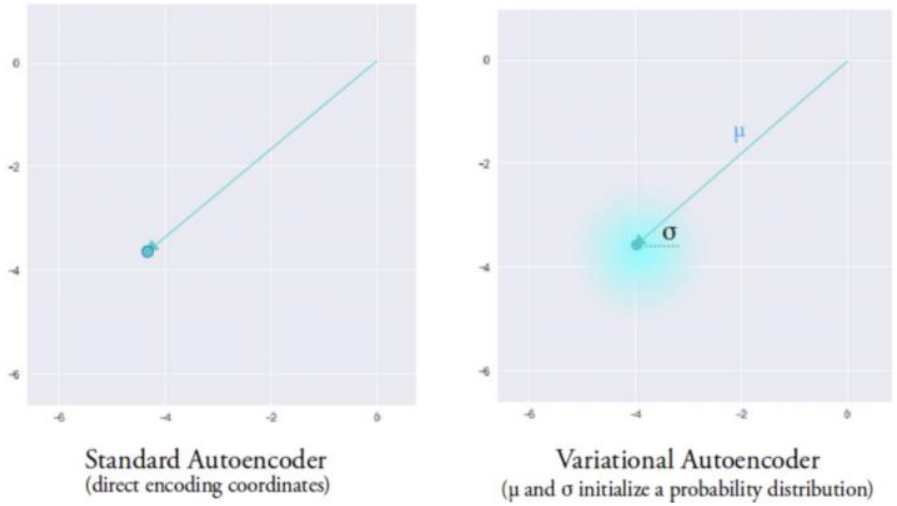




https://learnopencv.com/variational-autoencoder-in-tensorflow/

Variational Autoencoder (VAE)

- **Discrete latent vector (Standard auto-encoder) and a standard normal distribution (VAE)**
  - Instead of a single point, the VAE covers a certain area: a sample from anywhere in the area will be very similar to the original input.



- **Why normal distribution?**
  - We want to push the auto-encoder to have codings that look as though they were sampled from a simple Gaussian distribution. (assume that our dataset would inherently follow a distribution similar to the normal distribution.)
  - Enforcing the latent variables to follow a normal distribution in VAE is very common and works the best.

Variational Autoencoder (VAE)

- **Objective Function of VAE**
  - Unit Gaussian Distribution $\mathcal{N}(0, 1)$, and
  - Minimize the reconstruction error $\frac{1}{N}\sum_{i=1}^{N}(X_i - \hat{X}_i)^2$.
- **VAE's total loss**
  - **Loss = Re-construction_loss + KL_divergence_loss**

$$L_{MSE}(\theta, \phi) = \frac{1}{N}\sum_{i=1}^{N}\Big(x_i - f_\theta(g_\phi(x_i))\Big)^2 \quad \text{or} \quad \text{CE (Cross Entropy)}$$

$$L_{KL}[G(Z_\mu, Z_\sigma)\|\mathcal{N}(0,1)] = -0.5 * \sum_{i=1}^{N} 1 + log(Z_{\sigma_i}^2) - Z_{\mu_i}^2 - Z_{\sigma_i}^2$$

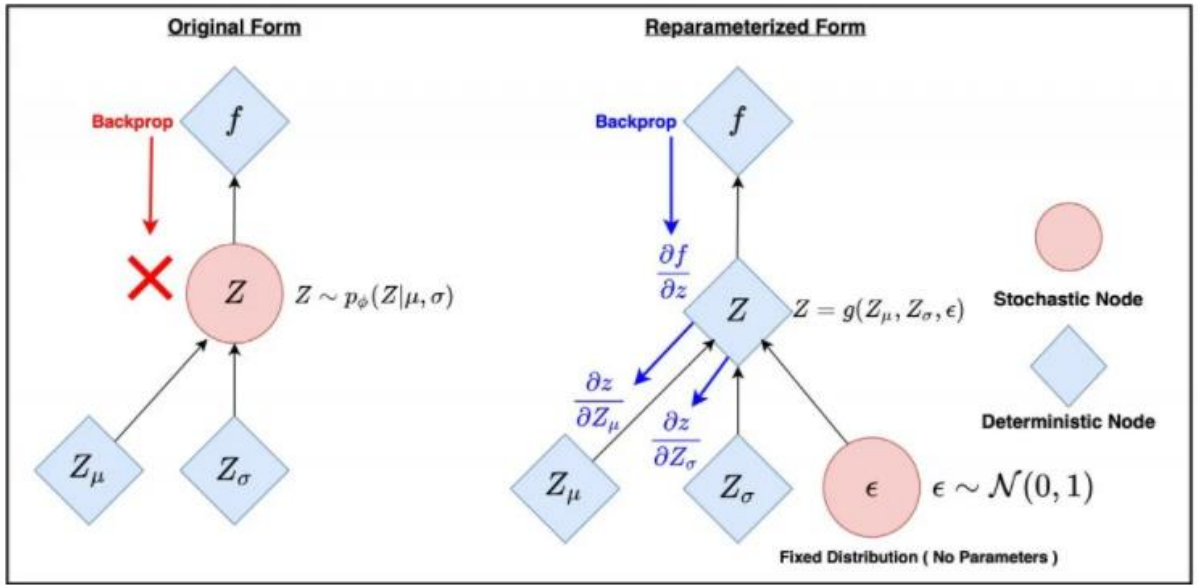
```
kl_loss =  -0.5 * numpy.sum(1 + numpy.log(Z_sigma ** 2) - numpy.square(Z_mean)
- numpy.exp(np.log(Z_sigma ** 2), axis = 1)

kl_loss =  -0.5 * numpy.sum(1 + numpy.log(Z_sigma ** 2) - numpy.square(Z_mean)
- Z_sigma ** 2, axis = 1)
```

Variational Autoencoder (VAE)

- **Re-parameterization Trick**
  - Sampling prevents backpropagation and their training.
  - **Trick**: convert the random node $\boldsymbol{Z}$ to a deterministic node ($\boldsymbol{Z}_\mu$ and $\boldsymbol{Z}_\sigma$ remain as the learnable parameters while still maintaining the stochasticity of the entire system via ε.)

$$\mathrm{Z} = \mathrm{Z}_\mu + Z_\sigma^2 \odot \varepsilon \qquad (\text{Here, } \varepsilon \sim \mathcal{N}(0,1) \text{ and } \odot \text{ is element-wise multiplication.})$$



Variational Autoencoder (VAE)

- **KL Divergence**
  - 두 확률 분포의 다른 정도 (= Relative Entropy)
  - 두 분포가 Gaussian 일 경우 간략하게 표현 가능

$$q_\theta(z|x_i) \rightarrow \frac{1}{\sqrt{2\pi\sigma_q^2}} \exp\left(-\frac{(x-\mu_q)^2}{2\sigma_q^2}\right)$$

$$p(z) \rightarrow \frac{1}{\sqrt{2\pi\sigma_p^2}} \exp\left(-\frac{(x-\mu_p)^2}{2\sigma_p^2}\right)$$

$$\sigma_p = 1 \text{ and } \mu_p = 0.$$

$$-D_{KL}(q_\theta(z|x_i)||p(z)) =$$

$$\int \frac{1}{\sqrt{2\pi\sigma_q^2}} \exp\left(-\frac{(x-\mu_q)^2}{2\sigma_q^2}\right) \log\left(\frac{\frac{1}{\sqrt{2\pi\sigma_p^2}} \exp\left(-\frac{(x-\mu_p)^2}{2\sigma_p^2}\right)}{\frac{1}{\sqrt{2\pi\sigma_q^2}} \exp\left(-\frac{(x-\mu_q)^2}{2\sigma_q^2}\right)}\right) dz$$

$$= \int \frac{1}{\sqrt{2\pi\sigma_q^2}} \exp\left(-\frac{(x-\mu_q)^2}{2\sigma_q^2}\right) \times$$

$$\left\{-\frac{1}{2}\log(2\pi) - \log(\sigma_p) - \frac{(x-\mu_p)^2}{2\sigma_p^2} + \frac{1}{2}\log(2\pi) + \log(\sigma_q) + \frac{(x-\mu_q)^2}{2\sigma_q^2}\right\} dz$$

$$-D_{KL}(q_\theta(z|x_i)||p(z)) = \log(\sigma_q) - \frac{\sigma_q^2 + \mu_q^2}{2} + \frac{1}{2}$$

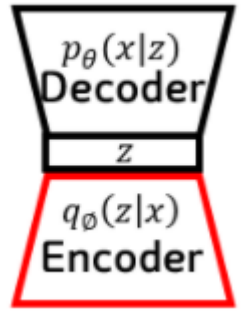
$$= \frac{1}{2}\log(\sigma_q^2) - \frac{\sigma_q^2 + \mu_q^2}{2} + \frac{1}{2}$$

$$= \frac{1}{2}\left[1 + \log(\sigma_q^2) - \sigma_q^2 - \mu_q^2\right]$$

Variational Autoencoder (VAE)

- **VAE Loss function**

$$L_i(\phi, \theta, x_i) = \underbrace{-\mathbb{E}_{q_\phi(z|x_i)}[\log(p_\theta(x_i|z))]}_{\text{Reconstruction Error}} + \underbrace{KL(q_\phi(z|x_i)||p(z))}_{\text{Regularization}}$$



$$\mathcal{L} = -\sum_{j=1}^{J} \frac{1}{2}\left[1 + \log\left(\sigma_i^2\right) - \sigma_i^2 - \mu_i^2\right] - \frac{1}{L}\sum_{l} E_{\sim q_\emptyset(z|x_i)}\left[\log p(x_i|z^{(i,l)})\right]$$

$$(\theta^*, \phi^*) = argmin_{(\theta,\phi)}\mathcal{L}(\theta, \phi)$$

Cross entropy

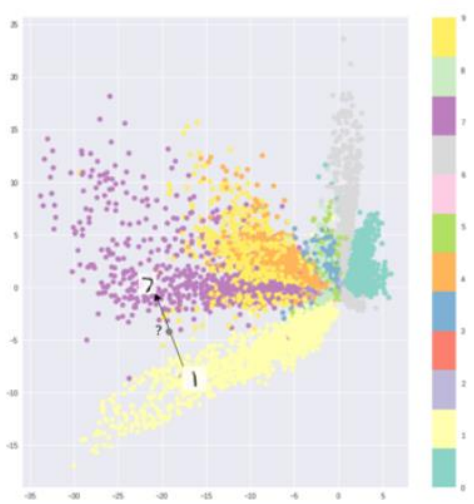
L: number of samples
J: dim of latent vector z

Ref: https://arxiv.org/pdf/1907.08956.pdf

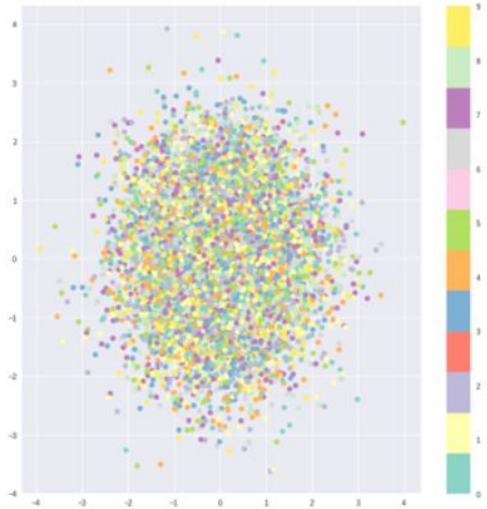
Variational Autoencoder (VAE)

$$\mathcal{L}(x, \hat{x}) + \beta \sum_j KL(q_j(z|x) || N(0,1))$$

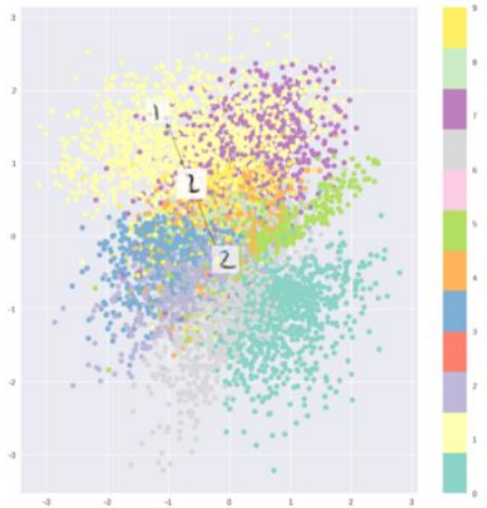
Only reconstruction loss



Only KL divergence



Combination



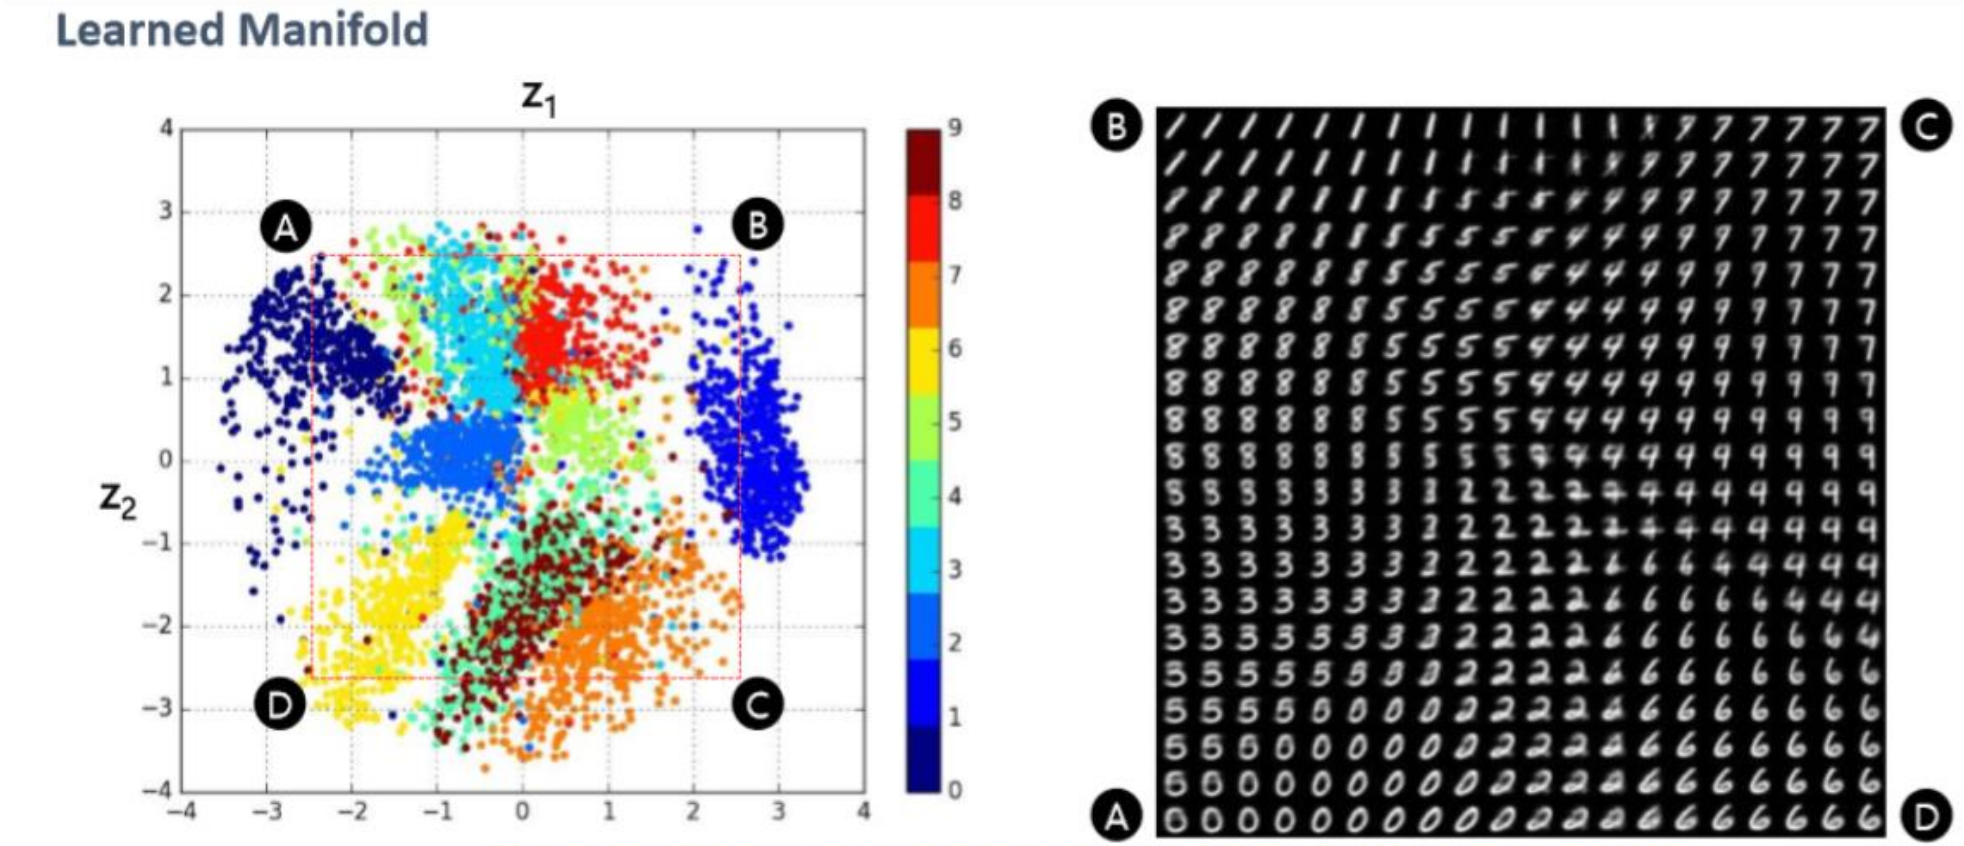
- Focus only on reconstruction loss, and allows the decoder be able to reproduce the original handwritten digits.
- there are areas in latent space which don't represent *any* of our observed data

- Focus only on KL divergence loss, and describe every observation using the same Gaussian (e.g. same characteristics)
- failed to describe the original data

https://www.jeremyjordan.me/variational-autoencoders/

Variational Autoencoder (VAE)

- **An example of well-trained VAE with MNIST dataset**



학습이 잘 되었을 수록 2D공간에서 같은 숫자들을 생성하는 z들은 뭉쳐있고,
다른 숫자들은 생성하는 z들은 떨어져 있어야 한다.

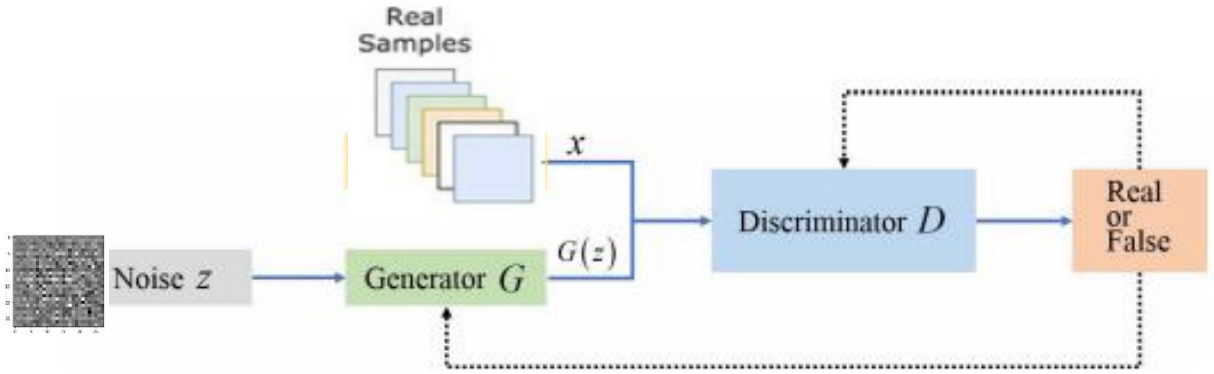
https://github.com/hwalsuklee/tensorflow-mnist-VAE

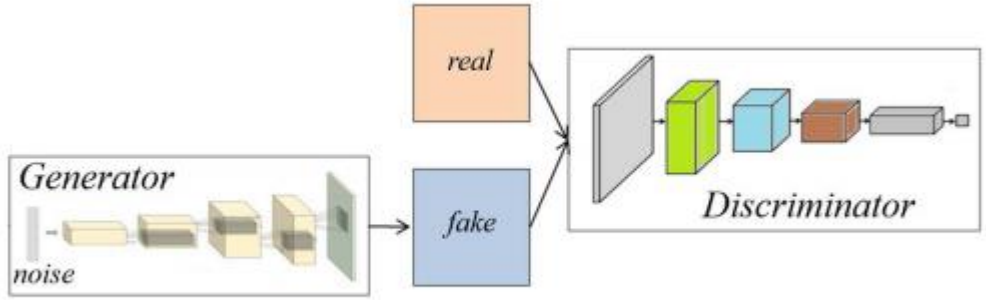
Variational Autoencoder (VAE)

- **Another example**
  - Gradually changing hair color and sunglasses to a face
  - https://github.com/compthree/variational-autoencoder

GAN

- **Generative Adversarial Network (GAN)**
  - Loss function: to make real(D(x)) close to 1, and fake(D(G(z)) close to 0
  - Discriminator: binary classifier (1: real, 0: fake)
  - Two separated optimizers





$$\min_G \max_D V(D,G) = \mathbb{E}_{\boldsymbol{x}\sim P_{\text{data}}}[\log D(\boldsymbol{x})] + \mathbb{E}_{\boldsymbol{z}\sim P_{\text{noise}}}\left[\log\left(1 - D(G(\boldsymbol{z}))\right)\right]$$

$$H_p(q) = -\frac{1}{N}\sum_{i=1}^{N} y_i \cdot log(p(y_i)) + (1-y_i)\cdot log(1-p(y_i))$$

yi=1 의 loss function

yi=0 의 loss function

GAN

- **Generative Adversarial Network (GAN)**

$$\min_G \max_D V(D, G) = \mathbb{E}_{\boldsymbol{x} \sim P_{\text{data}}}[\log D(\boldsymbol{x})] + \mathbb{E}_{\boldsymbol{z} \sim P_{\text{noise}}}\Big[\log\big(1 - D(G(\boldsymbol{z}))\big)\Big]$$

```
def discriminator_loss(real_output, fake_output):
    real_loss = cross_entropy(tf.ones_like(real_output), real_output)
    fake_loss = cross_entropy(tf.zeros_like(fake_output), fake_output)
    total_loss = real_loss + fake_loss
    return total_loss
```

true pred

```
def generator_loss(fake_output):
    return cross_entropy(tf.ones_like(fake_output), fake_output)
```

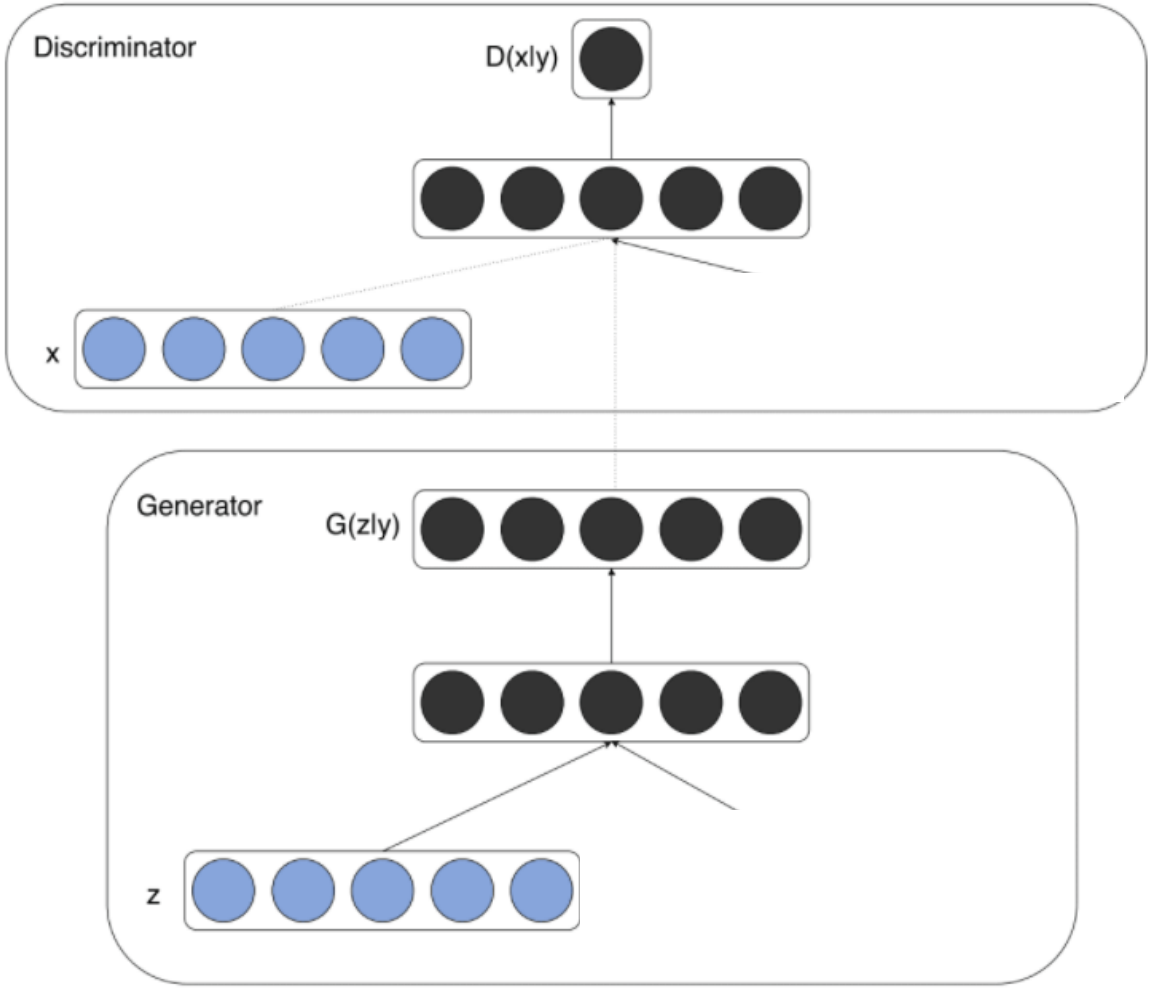
```
generator_optimizer = tf.keras.optimizers.Adam(1e-4)
discriminator_optimizer = tf.keras.optimizers.Adam(1e-4)
```

[ref: https://www.tensorflow.org/tutorials/generative/dcgan?hl=ko]

(Unconditional) GAN

$$\min_G \max_D V(D,G) = \mathbb{E}_{\boldsymbol{x}\sim p_{\text{data}}(\boldsymbol{x})}[\log D(\boldsymbol{x})] + \mathbb{E}_{\boldsymbol{z}\sim p_{\boldsymbol{z}}(\boldsymbol{z})}[\log(1 - D(G(\boldsymbol{z})))]$$

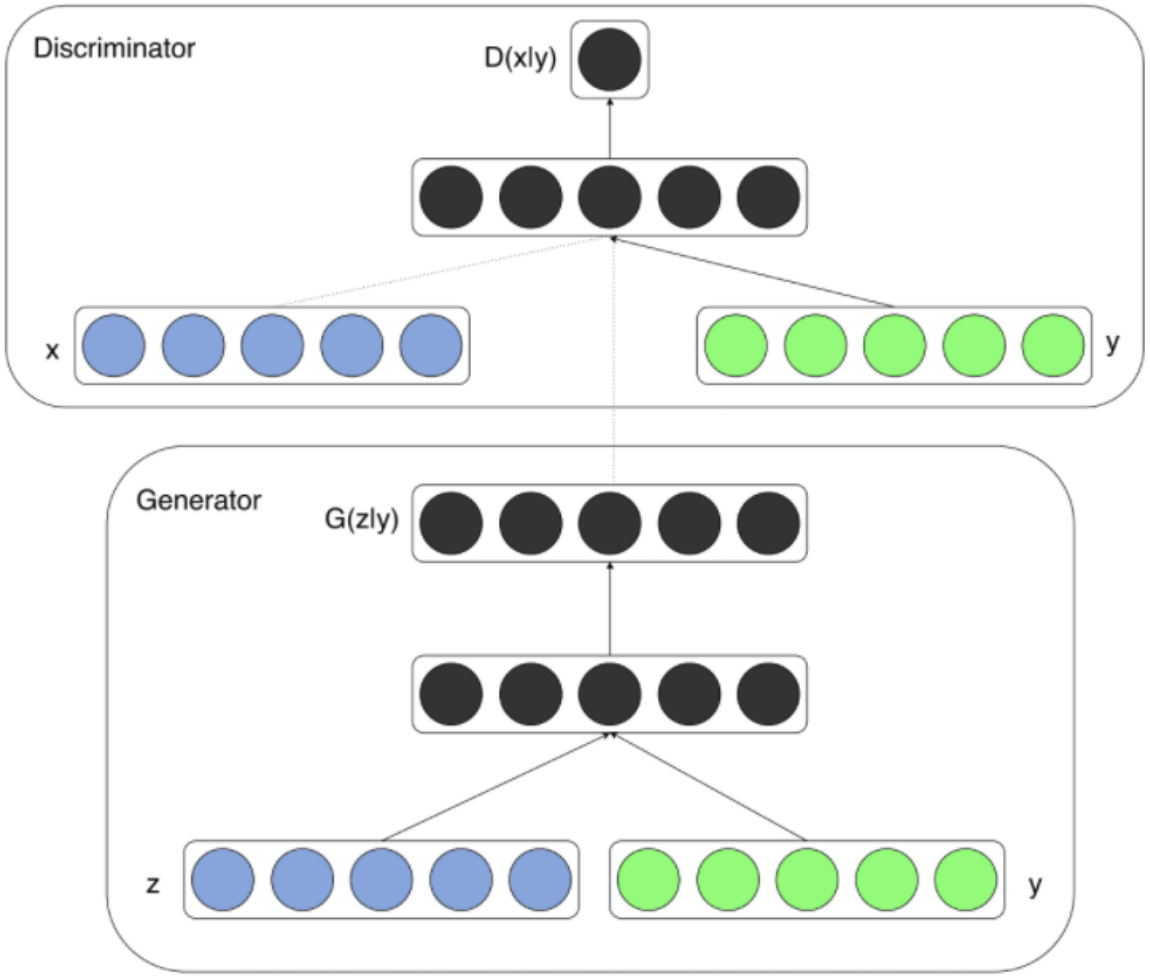
- Expectation
- x is sampled from real data
- Probability of D(real)
- z is sampled from N(0, 1)
- Probability of D(fake)
- fake



Example of a Conditional Generator and a Conditional Discriminator in a Conditional Generative Adversarial Network. Taken from Conditional Generative Adversarial Nets, 2014.

Conditional GAN (cGAN)

$$min_G max_D V(D,G) = \mathbb{E}_{x \sim p_{data}(x)}[logD(x|y)] + \mathbb{E}_{x \sim p_z(z)}[log(1 - D(G(z|y)))]$$



Example of a Conditional Generator and a Conditional Discriminator in a Conditional Generative Adversarial Network. Taken from Conditional Generative Adversarial Nets, 2014.
